Classical Optimal Transportation Theory

Let $\mu \in \mathcal{P}(X)$ and $\nu \in \mathcal{P}(Y)$ $(X \subseteq \mathbb{R}^n$ and $Y \subseteq \mathbb{R}^n)$, the Optimal Transport (OT) problem is defined as follows

$$(\mathcal{MK}) \quad \mathcal{E}_{c}(\mu,\nu) = \inf \left\{ \mathcal{E}_{c}(\gamma) \mid \gamma \in \Pi(\mu,\nu) \right\}$$
(1)

where $\Pi(\mu, \nu) := \{\gamma \in \mathcal{P}(X \times Y) | \quad \pi_{1,\sharp}\gamma = \mu, \ \pi_{2,\sharp}\gamma = \nu\}$ and $\mathcal{E}_c(\gamma) := \int c(x_1, x_2) d\gamma(x_1, x_2).$

Solution à la Monge : the transport plan γ is deterministic (or à la Monge) if $\gamma = (Id, T)_{\sharp}\mu$ where $T_{\sharp}\mu = \nu$.

The Multi-Marginal Optimal Transportation

Let us take N probability measures $\mu_i \in \mathcal{P}(X)$ with $i = 1, \dots, N$ and $c : X^N \to [0, +\infty]$ a continuous cost function. Then the multi-marginal OT problem reads as:

$$(\mathcal{MK}_N) \quad \mathcal{E}_c(\mu_1, \cdots, \mu_N) = \inf \left\{ \mathcal{E}_c(\gamma) \mid \gamma \in \Pi_N(\mu_1, \cdots, \mu_N) \right\}$$
(2)

where $\Pi_N(\mu_1, \dots, \mu_N)$ denotes the set of couplings $\gamma(x_1, \dots, x_N)$ having μ_i as marginals and

$$\mathcal{E}_{c}(\gamma) := \int c(x_{1}, \cdots, x_{N}) d\gamma(x_{1}, \cdots, x_{N})$$

Solution à la Monge : $\gamma = (Id, T_2, \dots, T_N)_{\sharp} \mu_1$ where $T_{i\sharp} \mu_1 = \mu_i$.

Why is it a difficult problem to treat? Example : N = 3, d = 1, $\mu_i = \mathcal{L}_{[0,1]} \forall i$ and $c(x_1, x_2, x_3) = |x_1 + x_2 + x_3|^2$.

- Uniqueness fails (Simone Di Marino, Augusto Gerolin, and Luca Nenna 2017);
- ∃ T_i optimal, are not differentiable at any point and they are fractal maps ibid., Thm 4.6

The Multi-Marginal Optimal Transportation

Let us take N probability measures $\mu_i \in \mathcal{P}(X)$ with $i = 1, \dots, N$ and $c : X^N \to [0, +\infty]$ a continuous cost function. Then the multi-marginal OT problem reads as:

$$(\mathcal{MK}_N) \quad \mathcal{E}_c(\mu_1, \cdots, \mu_N) = \inf \left\{ \mathcal{E}_c(\gamma) \mid \gamma \in \Pi_N(\mu_1, \cdots, \mu_N) \right\}$$
(2)

where $\Pi_N(\mu_1, \dots, \mu_N)$ denotes the set of couplings $\gamma(x_1, \dots, x_N)$ having μ_i as marginals and

$$\mathcal{E}_{c}(\gamma) := \int c(x_{1}, \cdots, x_{N}) d\gamma(x_{1}, \cdots, x_{N})$$

Solution à la Monge : $\gamma = (Id, T_2, \ldots, T_N)_{\sharp} \mu_1$ where $T_{i\sharp} \mu_1 = \mu_i$.

Why is it a difficult problem to treat? Example : N = 3, d = 1, $\mu_i = \mathcal{L}_{[0,1]} \ \forall i$ and $c(x_1, x_2, x_3) = |x_1 + x_2 + x_3|^2$.

- Uniqueness fails (Simone Di Marino, Augusto Gerolin, and Luca Nenna 2017);
- ∃ *T_i* optimal, are not differentiable at any point and they are fractal maps ibid., Thm 4.6

The Multi-Marginal Optimal Transportation

Let us take N probability measures $\mu_i \in \mathcal{P}(X)$ with $i = 1, \dots, N$ and $c : X^N \to [0, +\infty]$ a continuous cost function. Then the multi-marginal OT problem reads as:

$$(\mathcal{MK}_N) \quad \mathcal{E}_c(\mu_1, \cdots, \mu_N) = \inf \left\{ \mathcal{E}_c(\gamma) \mid \gamma \in \Pi_N(\mu_1, \cdots, \mu_N) \right\}$$
(2)

where $\Pi_N(\mu_1, \dots, \mu_N)$ denotes the set of couplings $\gamma(x_1, \dots, x_N)$ having μ_i as marginals and

$$\mathcal{E}_{c}(\gamma) := \int c(x_{1}, \cdots, x_{N}) d\gamma(x_{1}, \cdots, x_{N})$$

Solution à la Monge : $\gamma = (Id, T_2, ..., T_N)_{\sharp} \mu_1$ where $T_{i\sharp} \mu_1 = \mu_i$.

Why is it a difficult problem to treat? Example : N = 3, d = 1, $\mu_i = \mathcal{L}_{[0,1]} \forall i$ and $c(x_1, x_2, x_3) = |x_1 + x_2 + x_3|^2$.

- Uniqueness fails (Simone Di Marino, Augusto Gerolin, and Luca Nenna 2017);
- ∃ *T_i* optimal, are not differentiable at any point and they are fractal maps ibid., Thm 4.6

The dual formulation of (\mathcal{MK})

We consider the 2 marginals case for simplicity. The (\mathcal{MK}) problem admits a dual formulation:

$$\sup \left\{ \mathcal{J}(\phi,\psi) \mid (\phi,\psi) \in \mathcal{K} \right\}.$$
(3)

where

$$\mathcal{J}(\phi,\psi) := \int_X \phi d\mu(x) + \int_Y \psi d\nu(y)$$

and \mathcal{K} is the set of bounded and continuous functions ϕ, ψ such that $\phi(x) + \psi(y) \leq c(x, y)$.

Remark

Notice that the constraint on a couple (ϕ, ψ) may be rewritten as

$$\psi(y) \le \inf_{x} c(x, y) - \phi(x) := \phi^{c}(y).$$

So for an admissible couple (ϕ, ψ) one has $\mathcal{J}(\phi, \phi^c) \geq \mathcal{J}(\phi, \psi)$

Some applications

- The Wasserstein barycenter problem can be rewritten as a MMOT problem (see (Agueh and G. Carlier 2011)): statistics, machine learning, image processing;
- Matching for teams problem (see (Guillaume Carlier and Ekeland 2010)): economics. The transport plan γ matches individuals from each team μ_i minimizing a given cost;
- In Density Functional Theory: the electron-electron repulsion (see (Buttazzo, De Pascale, and Paola Gori-Giorgi 2012; C. Cotar, G. Friesecke, and C. Klüppelberg 2013)). The plan γ(x₁,...,x_N) returns the probability of finding electrons at position x₁,...,x_N;
- Incompressible Euler Equations (Yann Brenier 1989) : $\gamma(\omega)$ gives "the mass of fluid" which follows a path ω . See also (Jean-David Benamou, Guillaume Carlier, and Luca Nenna 2018).
- Variational Mean Field Games (J.-D. Benamou, G. Carlier, S. Di Marino, and L. Nenna 2018);
- etc...

01/09/2020

- Discrete-2-Discrete: the marginals μ have an atomic form, i.e.
 - $\mu(x) = \sum_i \mu_i \delta_{x_i}$ (and ν as well). **Remarks:**
 - The problem becomes a standard linear programming problem.
 - Works for any kind of cost function.
 - Can be easily generalized to the multi-marginal case.
- Continous-2-Discrete: $\mu = \overline{\mu} dx$ and $\nu(y) = \sum_i \nu_i \delta_{y_i}$. Remarks:
 - The semi-discrete approach (Mérigot 2011).
 - Used for generalized euler equations (kind of mmot problem) à la Brenier (Mérigot and Mirebeau 2016).
- Continous-2-Continous $\mu = \overline{\mu} d\kappa$ (and ν too). Remarks
 - The Benamou-Brenier formulation for Optimal Transport! (L-D. Benamou and Y. Brenier 2000)

- Discrete-2-Discrete: the marginals μ have an atomic form, i.e.

The discretized Monge-Kantorovich problem

Let's take $c_{ij} = c(x_i, y_j) \in \mathbb{R}^{M \times M}$ (*M* are the gridpoints used to discretize *X*) then the discretized (\mathcal{MK}), reads as

$$\min\{\sum_{i,j=1}^{M} c_{ij}\gamma_{ij} \mid \sum_{j=1}^{M} \gamma_{ij} = \mu_i \; \forall i, \; \sum_{i=1}^{M} \gamma_{ij} = \nu_j \; \forall j\}$$
(4)

and the dual problem

$$\max\{\sum_{i=1}^{M} \phi_{i}\mu_{i} + \sum_{j=1}^{M} \psi_{j}\nu_{j} \mid \phi_{i} + \psi_{j} \leq c_{ij} \forall (i,j) \in \{1, \cdots, M\}^{2}\}.$$
 (5)

Remarks

• The primal has M^2 unknowns and $M \times 2$ linear constraints.

• The dual has $M \times 2$ unknowns, but M^2 constraints.

Entropic Optimal Transport (Repetita iuvant!)

We present a numerical method to solve the regularized ((Jean-David Benamou, Guillaume Carlier, Marco Cuturi, Luca Nenna, and Gabriel Peyré 2015; M. Cuturi 2013; Galichon and Salanié 2009)) optimal transport problem (let us consider, for simplicity, 2 marginals)

$$\min_{\gamma \in \mathcal{C}} \sum_{i,j} c_{ij} \gamma_{ij} + \begin{cases} \epsilon \sum_{ij} \gamma_{ij} \log\left(\frac{\gamma_{ij}}{\mu_i \nu_j}\right) & \gamma \ge 0\\ +\infty & otherwise \end{cases}$$
(8)

where C is the matrix associated to the cost, γ is the discrete transport plan and C is the intersection between $C_1 = \{\gamma \mid \sum_j \gamma_{ij} = \mu_i\}$ and $C_2 = \{\gamma \mid \sum_i \gamma_{ij} = \nu_j\}$.

Remark: Think at ϵ as the temperature, then entropic OT is just OT at positive temperature.

$$\min_{\gamma \in \mathcal{C}} \mathcal{H}(\gamma | \bar{\gamma}) \tag{9}$$

Application I: MMOT for computing geodesics in the Wasserstein space

The three formulations of quadratic Optimal Transport

Three formulations of Optimal Transport problem) with the quadratic cost :

• The static

$$\inf\left\{\int_{X\times X}\frac{1}{2}|x-y|^2d\gamma\mid\gamma\in\Pi(\mu,\nu)\right\}$$

• The dynamic (Lagrangian) ($C = H^1([0,1];X)$ and $e_t:[0,1] o X)$

$$\inf\left\{\int_{\mathcal{C}}\int_0^1\frac{1}{2}|\dot{\omega}|^2dtdQ(\omega)\mid Q\in\mathcal{P}(\mathcal{C}),\ (e_0)_{\sharp}Q=\mu,\ (e_1)_{\sharp}Q=\nu\right\}$$

• The dynamic (Eulerian), aka the Benamou-Brenier formulation

$$\inf \int_0^1 \int_X \frac{1}{2} |v_t|^2 \rho_t dx dt \quad s.t. \ \partial_t \rho_t + \nabla \cdot (\rho_t v_t) = 0$$
$$\rho(0, \cdot) = \mu, \ \rho(1, \cdot) = \nu$$

Remarks:

• Consider the optimal solutions for the three formulations $\gamma^{\star}, Q^{\star}, \rho_t^{\star}$ then

$$\pi_t(x,y)_{\sharp}\gamma = (e_t)_{\sharp}Q = \rho_t^{\star},$$

where $\pi_t(x, y) = (1 - t)x + ty$.

if we discretise in time (let take *T* + 1 time steps) the Lagrangian formulation and imposing that ω(*t_i*) = *x_i* (*t_i* = *i*¹/_{*T*} for *i* = 0, · · · , *T*) we get the following discrete (in time) MMOT problem

$$\inf \int_{X^{T}} \frac{1}{2T} \sum_{i=0}^{T} |x_{i+1} - x_{i}|^{2} d\gamma(x_{0}, \cdots, x_{T}) \text{ s.t}$$
$$\gamma \in \mathcal{P}(X^{T+1}), \ \pi_{0,\sharp} \gamma = \mu, \ \pi_{T,\sharp} \gamma = \nu$$

Application II: MMOT and the electron-electron repulsion

Why Repulsive OT? The Density Functional Theory

Let denote by $\Psi(x_1, s_1, \ldots, x_N, s_N)$ the wavefunction for N electrons and $\gamma = N \sum_{s_1, \ldots, s_N \in \mathbb{Z}_2} |\Psi(x_1, s_1, \ldots, x_N, s_N)|^2 \stackrel{def}{=} \text{joint probability density of electrons}$ at positions $x_1, \ldots, x_N \in \mathbb{R}^d$. Then the **Density Functional Theory** consists in studying the following variational principle

Rayleigh-Ritz variational principle $E_0 = \inf_{\Psi \in H^2 ||\Psi||_2 = 1} \epsilon T[\Psi] + V_{ee}[\Psi] + \int \sum_{\Psi \in H^2 ||\Psi||_2 = 1} k V_{ext}(x_i) |\Psi|^2 dx$

 $T[\Psi]$ is the kinetic energy, v_{ext} is an external attractive potential and $V_{ee}[\Psi]$ is the electron-electron repulsion

$$V_{ee}[\Psi] = \int_{\mathbb{R}^{dN}} \sum_{s_1, \cdots, s_N \in \mathbb{Z}_2} \sum_{i < j} \frac{1}{|x_i - x_j|} |\Psi|^2 dx_1 \cdots dx_N.$$

Why Repulsive OT? The Density Functional Theory

Let denote by $\Psi(x_1, s_1, \ldots, x_N, s_N)$ the wavefunction for N electrons and $\gamma = N \sum_{s_1, \ldots, s_N \in \mathbb{Z}_2} |\Psi(x_1, s_1, \ldots, x_N, s_N)|^2 \stackrel{def}{=} \text{joint probability density of electrons}$ at positions $x_1, \ldots, x_N \in \mathbb{R}^d$. Then the **Density Functional Theory** consists in studying the following variational principle

Rayleigh-Ritz variational principle

$$E_0 = \inf_{\Psi \in H^1_a, ||\Psi||_2 = 1} \epsilon T[\Psi] + V_{ee}[\Psi] + \int \sum_{s_1, \cdots, s_N \in \mathbb{Z}_2} \sum_{i=1}^N v_{ext}(x_i) |\Psi|^2 dx \qquad (11)$$

 $T[\Psi]$ is the kinetic energy, v_{ext} is an external attractive potential and $V_{ee}[\Psi]$ is the electron-electron repulsion

$$V_{ee}[\Psi] = \int_{\mathbb{R}^{dN}} \sum_{s_1, \cdots, s_N \in \mathbb{Z}_2} \sum_{i < j} \frac{1}{|x_i - x_j|} |\Psi|^2 dx_1 \cdots dx_N.$$

The minimizing problem can be partitioned into a double minimization. First minimize over Ψ subject to a fixed ρ , then minimize over ρ :

$$E_0 = \inf_{\rho \in \mathcal{R}} F_{LL}[\rho] + \int v_{ext}(x)\rho(x)dx$$
(12)

where $\mathcal{R} := \{\rho | \rho \ge 0, \sqrt{\rho} \in H^1, \int \rho(x) = N\}$ and $F_{LL}[\rho]$ is the Levy-Lieb functional

$$F_{LL}[\rho] = \min_{\Psi \to \rho} \epsilon T[\Psi] + V_{ee}[\Psi]$$
(13)

25 / 32

Then we have (Bindini and De Pascale 2017; Codina Cotar, Gero Friesecke, and Claudia Klüppelberg 2018; Lewin 2018)...

Semiclassical limit

 $\lim_{\epsilon \to 0} F_{LL}[\rho] = \mathcal{M}\mathcal{K}[\rho]$

The minimizing problem can be partitioned into a double minimization. First minimize over Ψ subject to a fixed ρ , then minimize over ρ :

$$E_0 = \inf_{\rho \in \mathcal{R}} F_{LL}[\rho] + \int v_{ext}(x)\rho(x)dx$$
(12)

where $\mathcal{R} := \{\rho | \rho \ge 0, \sqrt{\rho} \in H^1, \int \rho(x) = N\}$ and $F_{LL}[\rho]$ is the Levy-Lieb functional

$$F_{LL}[\rho] = \min_{\Psi \to \rho} \epsilon T[\Psi] + V_{ee}[\Psi]$$
(13)

25 / 32

Then we have (Bindini and De Pascale 2017; Codina Cotar, Gero Friesecke, and Claudia Klüppelberg 2018; Lewin 2018)...

Semiclassical limit

 $\lim_{\epsilon \to 0} F_{LL}[\rho] = \mathcal{MK}[\rho]$

- \bullet We consider only wavefunctions Ψ real and spinless .
- $\gamma = |\Psi|^2$ is the **transport plan** and the electron-electron repulsion becomes $V_{ee}[\Psi] = \int_{\mathbb{R}^{dN}} \sum_{i < j} \frac{1}{|x_i - x_i|} \gamma(x_1, \cdots, x_N) dx_1 \cdots dx_N$
- The marginal density $\rho = \int_{\mathbb{R}^{d(N-1)}} \gamma dx_2 \cdots dx_N$ is the electron density and $\int_{\mathbb{R}^d} \rho(x) dx = 1$.
- $|\nabla \Psi|^2 = |\nabla \sqrt{\gamma}|^2 = \frac{1}{4} \frac{|\nabla \gamma|^2}{\gamma}$ so the kinetic energy can be re-written as

$$\mathcal{T}[\Psi] = \int_{\mathbb{R}^{dN}} \frac{1}{4} \frac{|\nabla \gamma|^2}{\gamma} dx_1 \cdots dx_N.$$

Luca Nenna (LMO)

01/09/2020

One can prove the following inequality

The Entropic Inequality (Seidl, Di Marino, A. Gerolin, L. Nenna, Giesbertz, and P. Gori-Giorgi 2017)

$$\min_{\gamma \to \rho} \int_{\mathbb{R}^{dN}} \epsilon \frac{1}{4} \frac{|\nabla \gamma|^2}{\gamma} + \sum_{i < j} \frac{1}{|x_i - x_j|} \gamma \ge \min_{\gamma \to \rho} \int_{\mathbb{R}^{dN}} \epsilon C \gamma \log(\gamma) + \sum_{i < j} \frac{1}{|x_i - x_j|} \gamma = \mathcal{H}(\gamma | \bar{\gamma}).$$
(14)

where $\int \frac{1}{4} \frac{|\nabla \gamma|^2}{\gamma} \ge C \int \gamma \log(\gamma)$ is the log-sobolev inequality (or Fisher information) and the entropic functional $\mathcal{H}(\gamma|\bar{\gamma})$ corresponds to minimize the Kullback-Leibler distance between γ and $\bar{\gamma} = e^{-\sum_{i < j} \frac{1}{|x_i - x_j|} \frac{1}{c_e}}$.

01/09/2020

Consider now the cost function

$$c(x_1,\cdots,x_N)=\sum_{i\neq j}rac{1}{|x_i-x_j|},$$

and $\mu_1 = \cdots = \mu_N = \rho$ (we refer to ρ as the electronic density) then the MMOT gives the electronic configuration (namely the optimal transport plan γ) which minimises the electron-electron repulsion.

Remarks:

- Since the cost is symmetric in the marginals then the dual problem reduces to look for only one potential;
- The cost is also radially symmetric which means that when ρ is radially symmetric then the d = 3 pb. reduces to a one dimensional pb;
- Existence of Monge solutions is still an open problem for d > 1;

Take the Coulomb cost and solve the regularized problem. Then as $\epsilon \to 0$ (N = 512), we have
